UNIVERSITY OF
CAMBRIDGE

Inverse decision modeling (understanding humans)

- Understanding, explaining & auditing decisions
- Giving quantitative accounts of past behavior
- Identifying “suboptimal” behavior
- Analyzing variation in practice
- Improving policies

Conventional decision-making analysis (replacing humans/guiding humans)

- Optimal control
- Reinforcement learning
- Apprenticeship learning
- Imitating behavior

Quantitative Epistemology (partnering with & empowering humans)

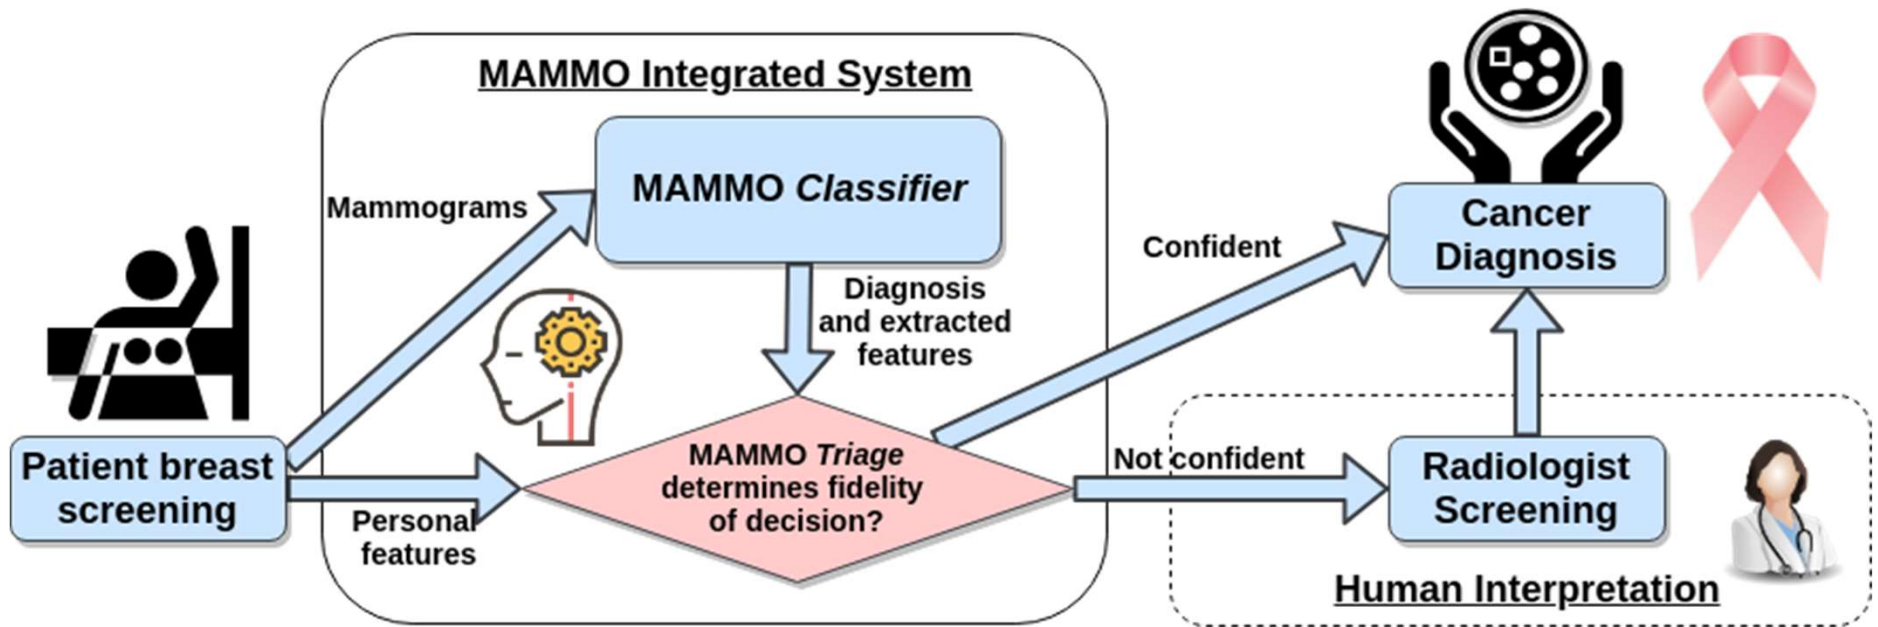

- *Help humans acquire better information*
- *Direct humans towards the right information*
- *Help humans evaluate and integrate diverse sources of information and turn them into decisions*
- *Learn various knowledge representations that humans use*
- *Identify each individual’s internal knowledge models and make the best use of that knowledge*
- *Representations to use when interacting with humans*
- *Aid human communication*
- *Help humans learn*
- ...

MAMMO: a framework for human-ML cooperation

[Kyono, vdS, ML4HC 2019]

[Kyono, Gilbert, vdS, JACR, 2019]

Machine learning for
mammography article named
"Best of 2020" by JACR

Who is better? Human (radiologist) or machine (classifier)?

Patient A

Radiologist & Classifier correct

Density: 39 (22)

Susp: malignant (suspicious)

Sign: spic. mass (spic. mass)

Cons: visible (visible)

Density: 43 (22)

Susp: normal (suspicious)

Sign: spic. mass (spic. mass)

Cons: visible (visible)

Patient B

Radiologist correct & Classifier wrong

Density: 49 (40)

Susp: normal (probably benign)

Sign: none (micro-calc)

Cons: not visible (barely)

Density: 49 (40)

Susp: normal (suspicious)

Sign: none (micro-calc)

Cons: not visible (visible)

Patient C

Radiologist wrong & Classifier correct

Density: 32 (14)

Susp: malignant (benign)

Sign: asym. dense (asym. dense)

Cons: visible (visible)

Density: 25 (14)

Susp: malignant (benign)

Sign: asym dense (asym. dense)

Cons: visible (visible)

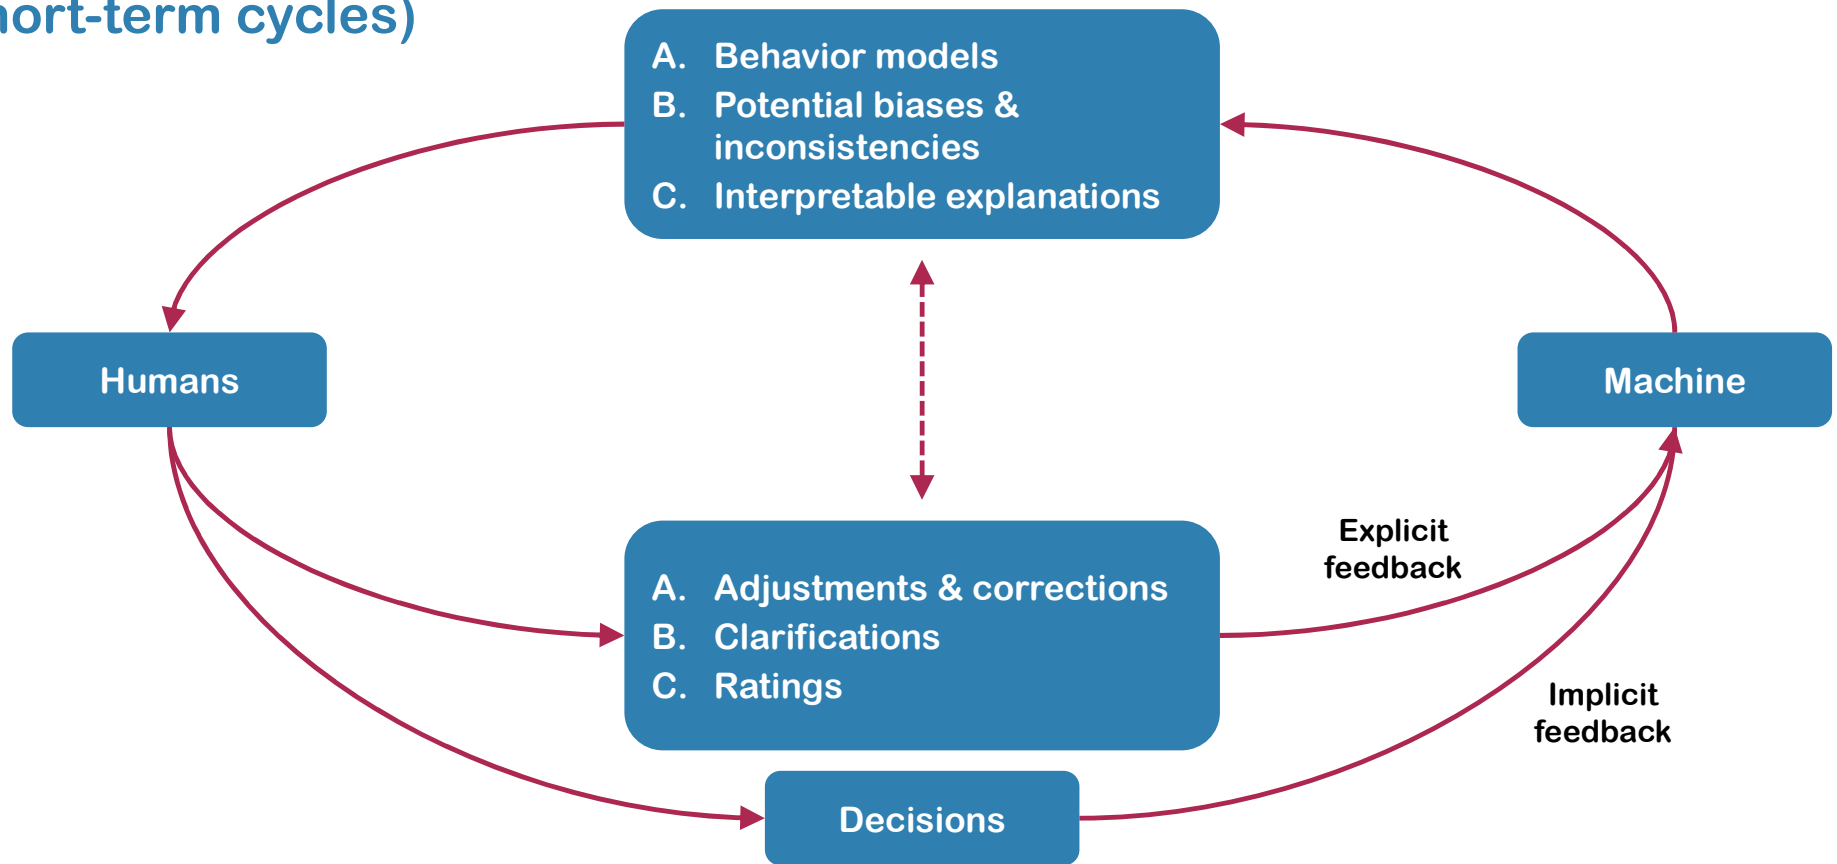

MAMMO enables various cooperation modes between humans and machines

MAMMO – Cooperation modes

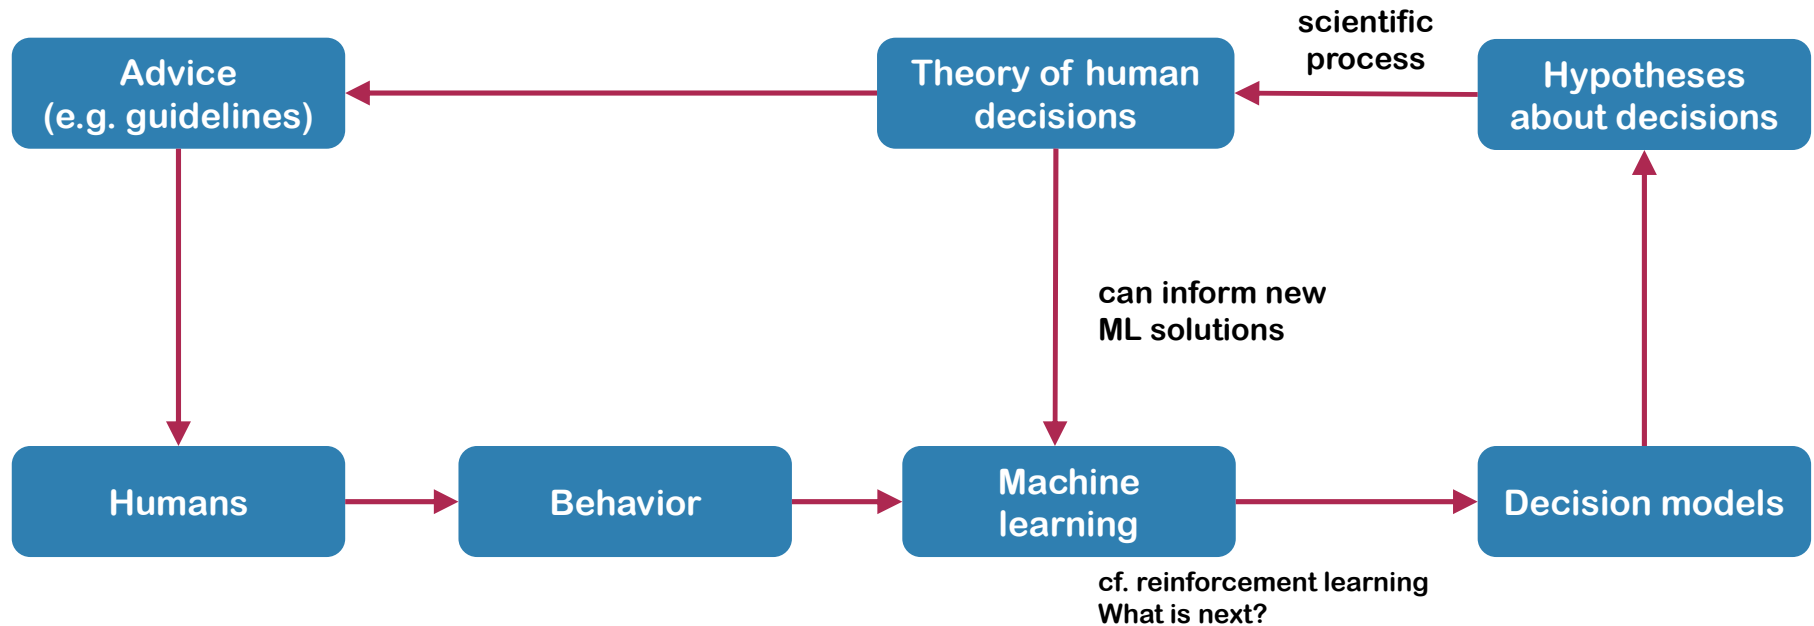

1. Radiologist + Classifier – both activated as double readers
2. Radiologist + Classifier – triaging - operating as a single reader (hybridized)

	Radiologist patients	<i>Classifier</i> patients	Cohen's κ	F1 score	TP	TN	FP	FN
Radiologist	1000	0	0.708	0.755	120	802	42	36
<i>Classifier</i>	0	1000	0.420	0.433	61	811	33	95
<i>Classifier</i> [®]	1000	1000	0.647	0.708	125	772	72	31
MAMMO	456	544	0.724	0.766	118	810	34	38

New human-machine partnership: Online operation (short-term cycles)

New human-machine partnership (long-term cycles)

Quantitative Epistemology: Our work so far

Agent = human		IDM framework (ICML'21)		
Method	Goal / motivating question	Planner	Normative params.	Descriptive params.
IAS (ICML'20)	How “timely” is agent decision making?	Timely active sensing	Deadline, cost of acquisition	Importance of accuracy, speed, efficiency
AVRIL (ICLR'21)	What reward function does the agent optimize?	RL planner	-	Reward function
CIRL (ICLR'21)	How important are various counterfactuals in making decisions?	Counterfactual RL planner	Counterfactuals	Importance weights
INTERPOLE (ICLR'21)	What are the subjective beliefs of the agent?	Policies based on decision boundaries	Interpretable state space	Decision dynamics & decision boundaries
IBRC (ICML'21)	How optimal is agent behavior relative to an “ideal” reward function?	Bounded rational planner	“Ideal” reward function	Flexibility, optimism, adaptivity
ICB (submitted)	How does agent’s behavior evolve over time?	Contextual bandit strategies	-	Time-varying beliefs over reward functions

Inverse decision modeling (IDM) – Learning Interpretable Representations of Behavior

Human decision-making is not perfect

- bounded rationality, cognitive biases

How can we help humans make better decisions?

- requires a **quantitative** account of the “imperfections” that necessitate correcting

Inverse decision modeling

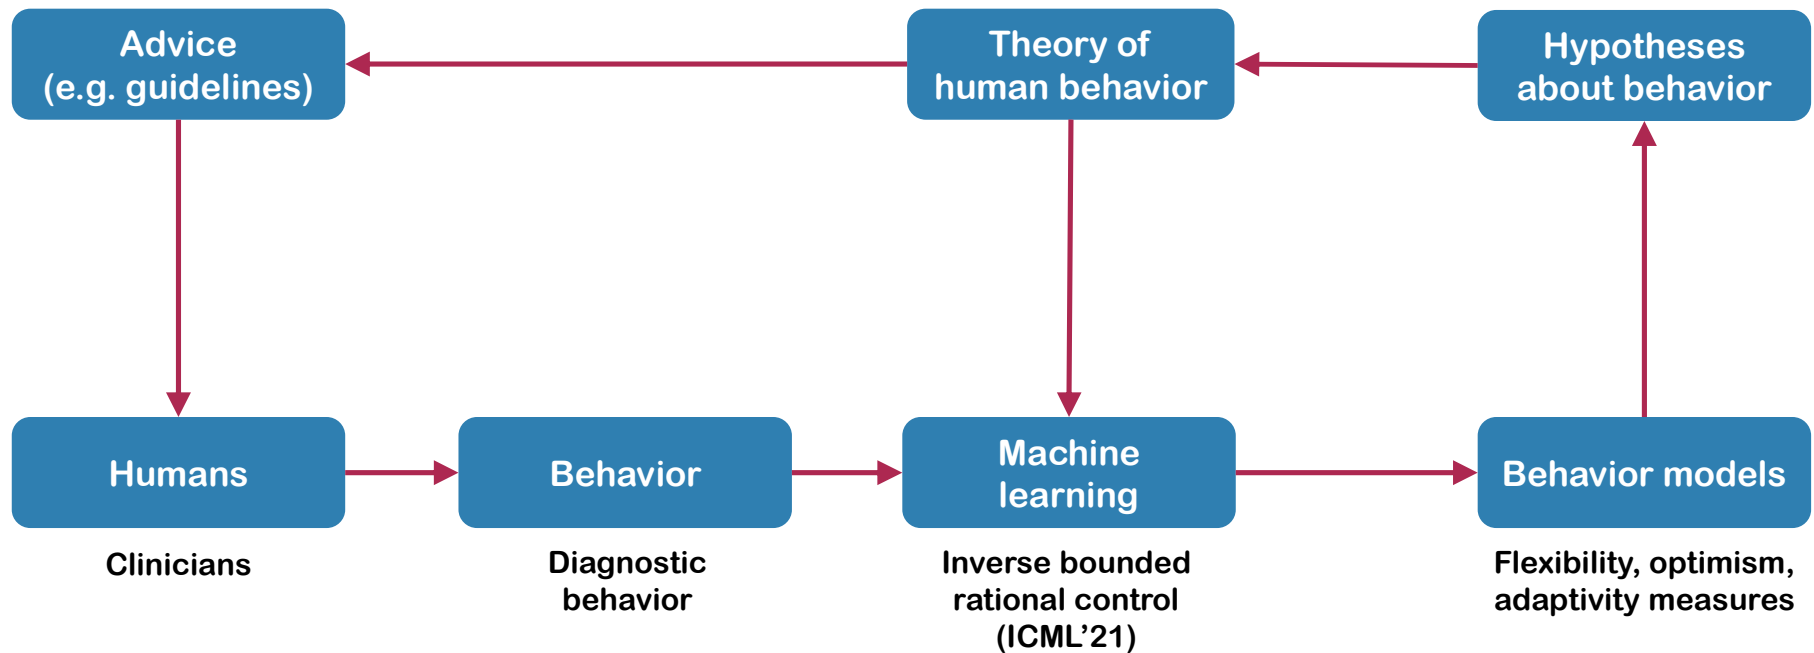

- general framework for learning representations of decision-making behavior
- enables us to describe existing behavior **relative to “ideal” behavior**

New human-machine partnership within the IDM framework (long-term cycles)

Why clinicians are overly pessimistic towards at-risk patients?

- Clinicians are overly pessimistic when diagnosing patients at risk.
- Optimism and confirmation bias lead to similar but differentiable behavior.

Conventional decision-making analysis

The “forward” problem:

- What constitutes ideal behavior?

The “inverse” problem:

- What does the existing behavior look like?

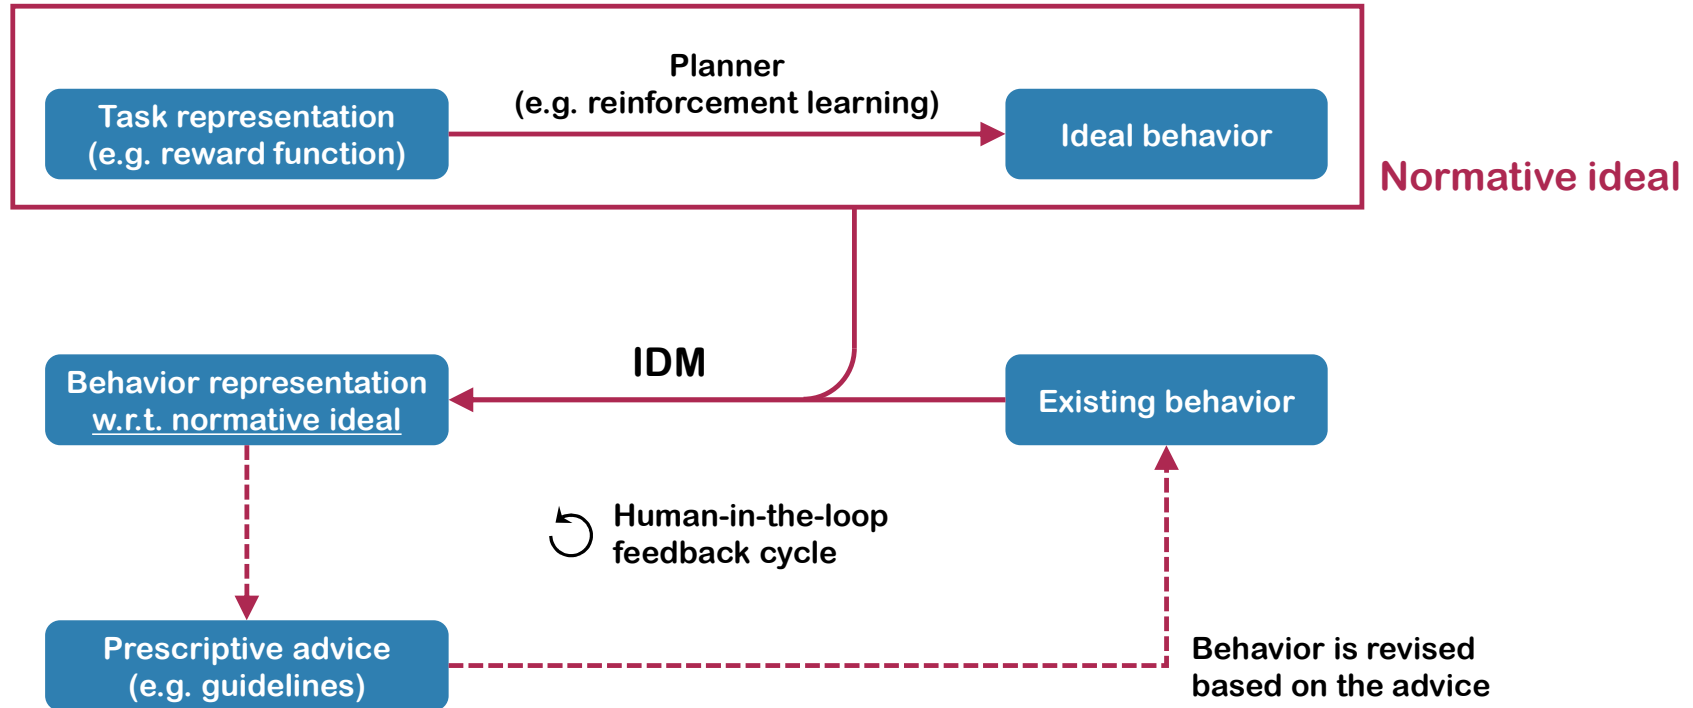

Existing solutions offer limited help

- forward solutions do not take human behavior into account
- inverse solutions focus on imitating human behavior

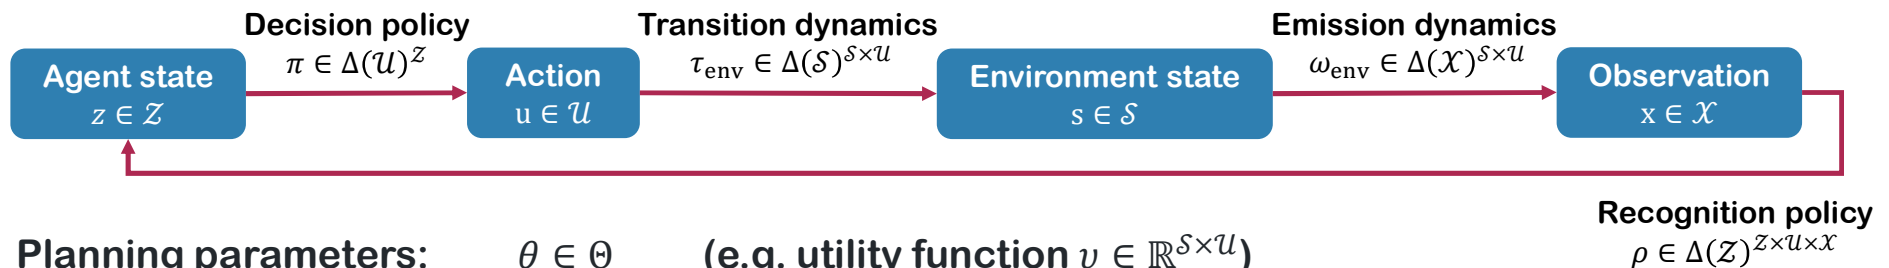

Inverse decision modeling

Planners

Problem setting:

- **Planning parameters:** $\theta \in \Theta$ (e.g. utility function $v \in \mathbb{R}^{\mathcal{S} \times \mathcal{U}}$)
- **Behavior:** $\phi_{\pi, \rho} \in \Phi = \Delta(\cup_t (\mathcal{X} \times \mathcal{U})^t)$

(Forward) planner:

$$F(\theta) = \phi_{\pi^*, \rho^*} \quad \text{where} \quad \pi^*, \rho^* = \operatorname{argmax}_{\pi, \rho} \mathcal{F}(\pi, \rho; \theta)$$

- e.g. reinforcement learning: $\mathcal{F}(\pi; \theta) = \mathbb{E}_{\pi}[\sum_t v(s_t, u_t)]$

Inverse planners

- Demonstrated behavior: $\phi_{\text{demo}} \in \Phi$
- Normative/descriptive params.: $\theta = (\theta_{\text{norm}}, \theta_{\text{desc}}) \in \Theta = \Theta_{\text{norm}} \times \Theta_{\text{desc}}$

Inverse planner:

$$\hat{\theta}_{\text{desc}} = \operatorname{argmax}_{\theta_{\text{desc}}} \mathcal{G}(\phi_{\text{demo}}, \phi_{\text{imit}} = F(\theta_{\text{norm}}, \theta_{\text{desc}}))$$

- e.g. distribution matching: $\mathcal{G}(\phi_{\text{demo}}, \phi_{\text{imit}}) = -D_{\text{KL}}(\phi_{\text{demo}} || \phi_{\text{imit}})$
- projection of ϕ_{demo} onto $\Phi_{\theta_{\text{norm}}} = F(\theta_{\text{norm}}, \Theta_{\text{desc}})$
- Subsumes a wide range of algorithms
- Opens up new possibilities for **interpretative** research on decision making

An application of IDM

Inverse reinforcement learning

- F = the RL planner
- $\theta_{\text{norm}} = \emptyset$
- $\theta_{\text{desc}} = v$ (reward/utility function)
- $\mathcal{G}(\phi_{\text{demo}}, \phi_{\text{imit}} = F(v)) = \mathbb{E}[V_v(\phi_{\text{demo}}) - V_v(\phi_{\text{imit}})]$

How “rational” does ϕ_{demo} appears to be in pursuing (the “ideal”) v ?

- F = a bounded rational planner
- $\theta_{\text{norm}} = v$
- $\theta_{\text{desc}} =$ measures of “rationality”
- Appropriate inverse planner G
- Inverse rational bounded control

Bounded rational control

Uncertain knowledge of the environment

- Unbiased prior: $\tilde{\sigma} \in \Delta(\mathcal{T}, \mathcal{O})$
- Biased specification policy: $\sigma(z, u) \in \Delta(\mathcal{T}, \mathcal{O})^{z, u}$

Recognition policy is given in terms of specification policy

- $q(z' | z, u) = \mathbb{E}_{\tau, \omega \sim \sigma(z, u), x' \sim \omega} [\rho_{\tau, \omega}(z' | z, u, x')]$
- $\rho_{\tau, \omega}$ could be Bayesian inference under perfect knowledge τ, ω

Bounded rational planner:

$$\begin{aligned} \text{maximize} \quad & \mathbb{E}_{\pi, \rho, \sigma} [\sum_t v(s_t, u_t)] \quad \text{s.t.} \quad \mathbb{E}_z [D_{\text{KL}}(\pi(\cdot | z) || \tilde{\pi})] < A && \longrightarrow \text{Decision complexity} \\ & \mathbb{E}_{z, u} [D_{\text{KL}}(\sigma(\cdot | z, u) || \tilde{\sigma})] < B && \longrightarrow \text{Specification complexity} \\ & \mathbb{E}_{z, u, \tau, \omega} [D_{\text{KL}}(q_{\tau, \omega}(\cdot | z, u) || \tilde{q})] < C && \longrightarrow \text{Recognition complexity} \end{aligned}$$

Bounded rational control

Value iteration:

$$V(z) \leftarrow \mathbb{E} \left[v(s, u) + \gamma V(z') - \underbrace{\alpha \log \frac{\pi(u|z)}{\tilde{\pi}(z)} - \beta \log \frac{\sigma(\tau, \omega|z, u)}{\tilde{\sigma}(z, u)} - \eta \log \frac{\varrho_{\tau, \omega}(z'|z, u)}{\tilde{q}(z')}}_{\text{Complexity terms}} \right]$$

- $1/\alpha$ is a measure of **flexibility**
- $1/\beta$ is a measure of **optimism**
- $1/\eta$ is a measure of **adaptivity**

Flexibility, optimism, adaptivity

- **Observations:** negative (x_-), positive (x_+)
- **Actions:** monitor ($u_="$), negative diagnosis (u_-), positive diagnosis (u_+)
- **Utility:** 10 for correct diagnoses, -36 for incorrect diagnosis, -1 for monitoring

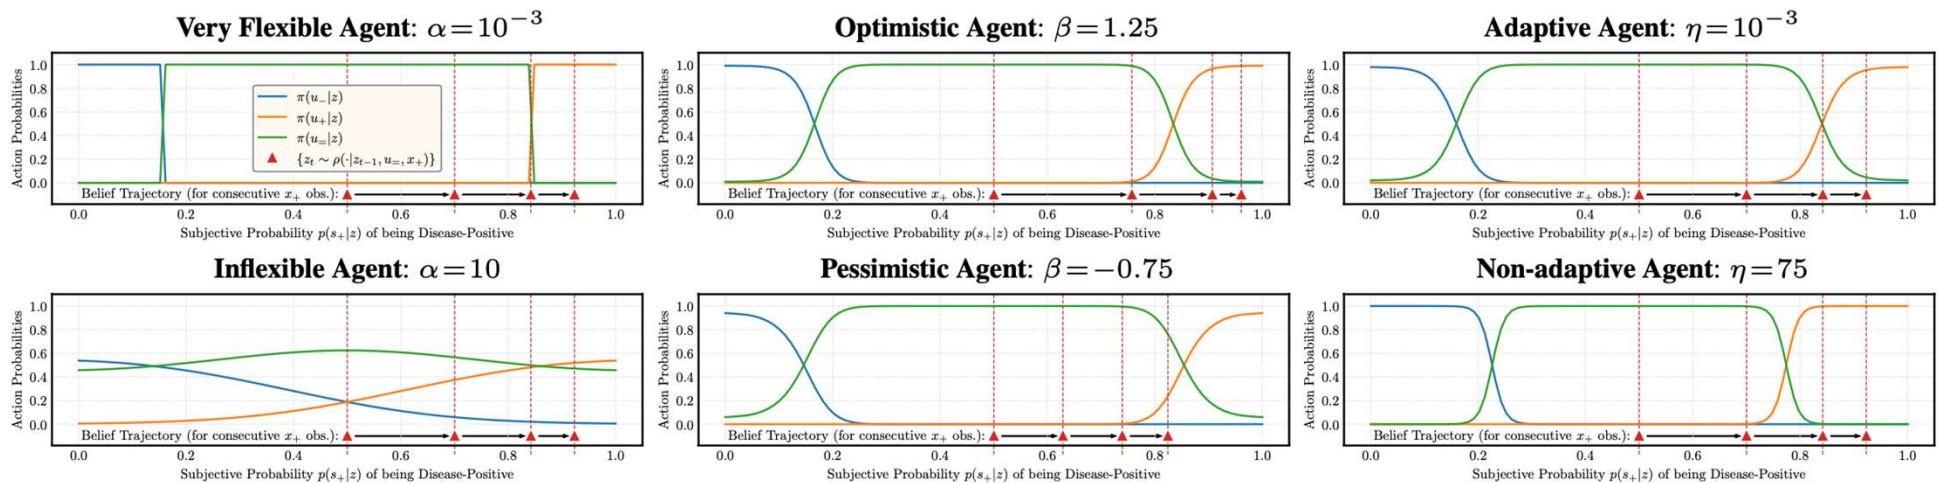

van_der_Schaar
\ LAB

vanderschaar-lab.com

Flexibility, optimism, adaptivity

- Observations: negative (x_-), positive (x_+)
- Actions: monitor (u_+), negative diagnosis (u_-), positive diagnosis (u_+)
- Utility: 10 for correct diagnoses, -36 for incorrect diagnosis, -1 for monitoring

(a) Effect of Flexibility, for a neutral ($\beta = 10^3$), adaptive ($\eta = 10^{-3}$) agent

cf. behavioral inconsistency

(b) Effect of Optimism, for a flexible ($\alpha = 0.5$), adaptive ($\eta = 10^{-3}$) agent

cf. over-/underreaction

(c) Effect of Adaptivity, for a flexible ($\alpha = 0.5$), neutral ($\beta = 10^3$) agent

cf. base rate neglect/confirmation bias

Inverse bounded rational control

How “rational” does ϕ_{demo} appears to be in pursuing (the “ideal”) v ?

Inverse bounded rational control:

- F = the bounded rational planner
- $\theta_{\text{norm}} = v$
- $\theta_{\text{desc}} = \alpha, \beta, \eta$
- $\mathcal{G}(\phi_{\text{demo}}, \phi_{\text{imit}}) = \mathbb{E}_{x, u \sim \phi_{\text{demo}}} [\mathbb{P}_{\phi_{\text{imit}}}(u_{1:T} || x_{1:T})]$

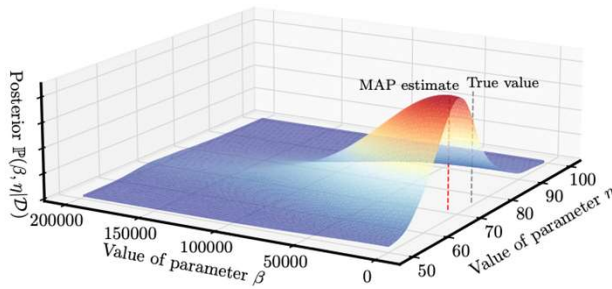

Learned α for various levels of flexibility

Differentiating non-adaptivity and optimism

Non-adaptivity and optimism lead to similar behavior.

Learned β, η for Non-adaptive Behavior

Learned β, η for Optimistic Behavior

Utilities estimated by IRL: 10 for correct diagnoses
-26±3 for incorrect diagnoses

10 for correct diagnoses
-27±3 for incorrect diagnoses

Illustrative use of IDM

IDM can be used as an investigative device for auditing and understanding human decision-making

Environment:

Diagnosing Alzheimer's disease

When to order an MRI?

- MRIs are informative but costly

$S = \{\text{NL, MCI, Dementia}\}$

$A = \{\text{MRI, No MRI}\}$

$Z = \text{Cognitive test results} \times \text{MRI outcomes}$

ADNI dataset

van_der_Schaar
\ LAB

vanderschaar-lab.com

UNIVERSITY OF

Pessimism when diagnosing Alzheimer's

Diagnosis of Alzheimer's:

When to order an MRI?

- MRIs are informative but costly

$\beta = 3.86$ for all patients

Clinicians appear to be **significantly less optimistic** when diagnosing:

- patients with the ApoE4 genetic risk factor ($\beta = 601.74$)
- female patients ($\beta = 920.70$)
- patients aged >75 ($\beta = 2265.30$)

Our other work within the IDM framework

Method	Goal / motivating question	Planner	Normative params.	Descriptive params.
IAS (ICML'20)	How “timely” does the agent make decisions?	Timely active sensing	Deadline, cost of acquisition	Importance of accuracy, speed, efficiency
AVRIL (ICLR'21)	What reward function does the agent optimize?	RL planner	-	Reward function
CIRL (ICLR'21)	How important are various counterfactuals in making decisions?	Counterfactual RL planner	Counterfactuals	Importance weights
INTERPOLE (ICLR'21)	What are the subjective beliefs of the agent?	Policies based on decision boundaries	Interpretable state space	Decision dynamics & decision boundaries
IBRC (ICML'21)	How rational the agent behaves relative to an “ideal” reward function?	Bounded rational planner	“Ideal” reward function	Flexibility, optimism, adaptivity
ICB (submitted to NeurIPS'21)	How does behavior evolve over time?	Contextual bandit strategies	-	Time-varying beliefs over reward functions

IDM defines a broad class of potential studies in behavior representation learning

The screenshot shows the website's navigation menu with links for 'The lab', 'Publications', 'Big ideas', 'News', 'Videos', 'Events', 'Software', 'Engagement sessions', 'Tutorials', 'Research pillars', 'Spotlights', 'Hub for Healthcare', and 'Contact'. The main banner features the text 'Quantitative epistemology: conceiving a new human-machine partnership' over a brain scan image. Below this, there are sections for 'Hub for Healthcare' and 'Engagement sessions'. The right side of the screenshot displays an article titled 'Decision trajectories for Alzheimer's patients', which includes a legend for belief simplex diagrams and four sub-diagrams (a-d) illustrating patient trajectories from Normal (NL) to Mild Cognitive Impairment (MCI) to Dementia. A legend defines symbols: a square for 'An MRI is more likely to be ordered', a circle for 'An MRI is ordered', a diamond for 'Final beliefs', a triangle for 'Belief simplex', a square with a dot for 'An MRI is less likely to be ordered', a red circle for 'An MRI is not ordered', a dashed arrow for 'Belief updates', and a dashed line for 'Decision boundary'. The sub-diagrams are: (a) Typical Normal Patient, (b) Typical Deteriorating Patient, (c) Patient is Diagnosed Late, and (d) Patient with High-value Tests. Below the diagrams, text explains the state space conditions and the role of the decision-maker's beliefs.
